IPv4 Address Lifetime Expectancy

Geoff Huston, APNIC 26 October 2005 ARIN XVI

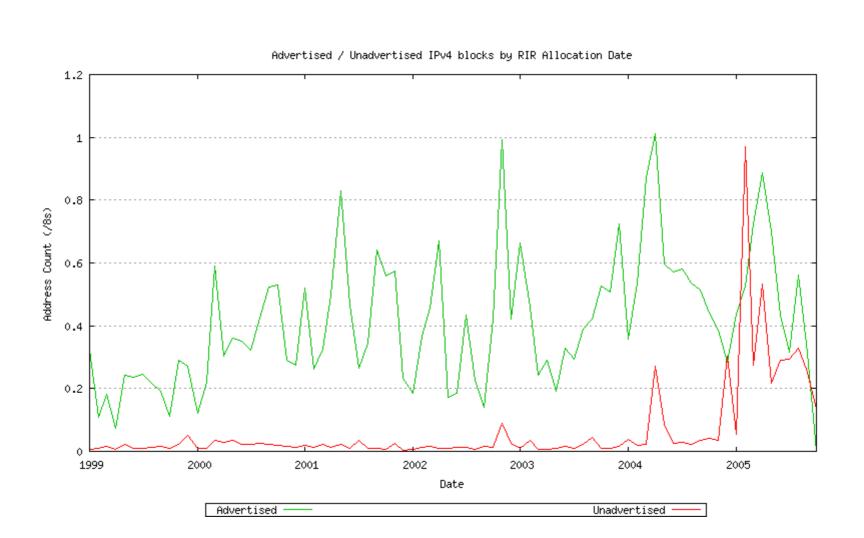

A look at the IPv4 data

- Use a fundamental assumption that <u>the driver</u> for address consumption is the public <u>Internet</u>, and that the growth of the Internet is reflected in address consumption demands
- Adjust the model to include each individual RIR's allocation behaviour over time
- Set the 'exhaustion' date at the point when any RIR cannot honour an address request

Current Status

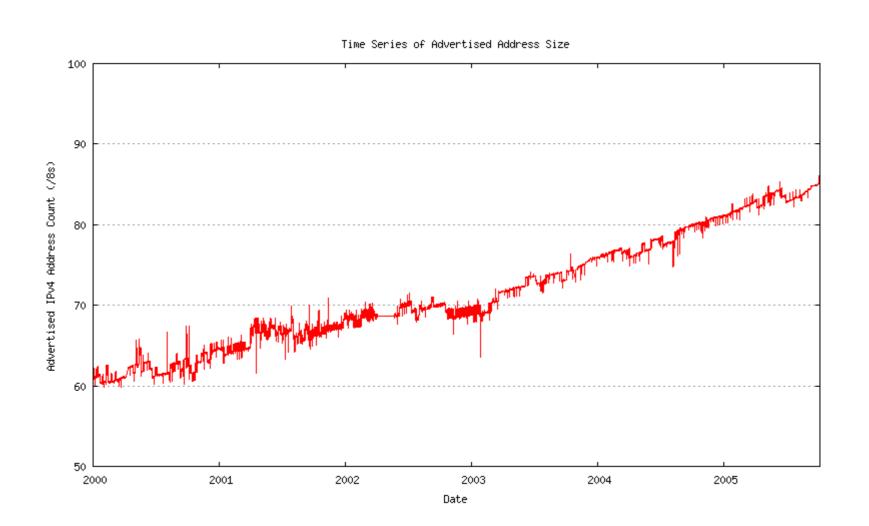

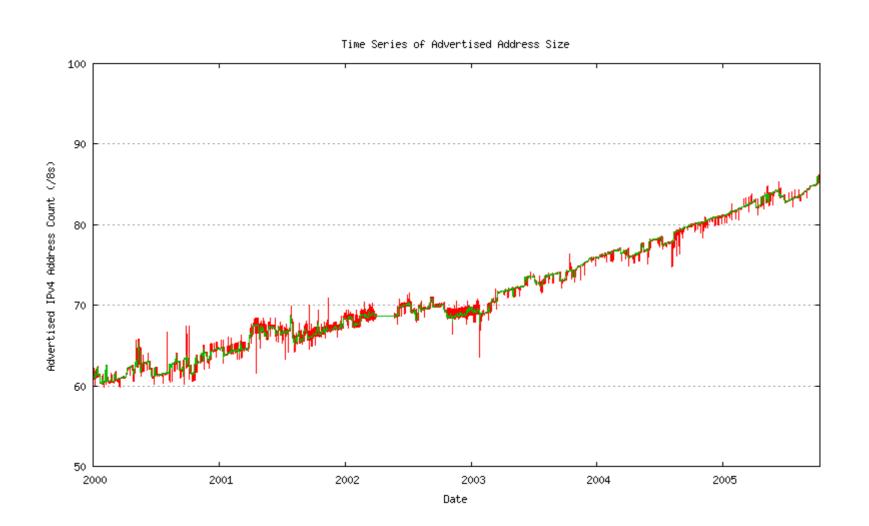

Advertised and Unadvertised Addresses

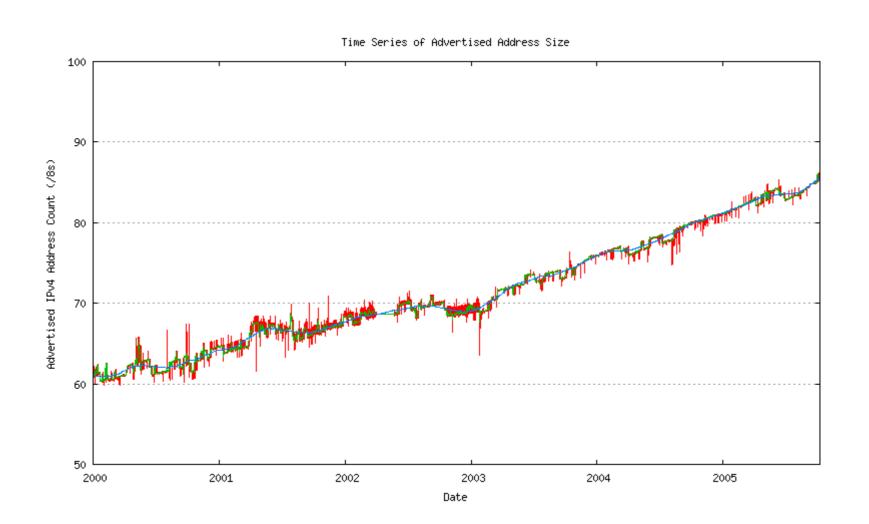

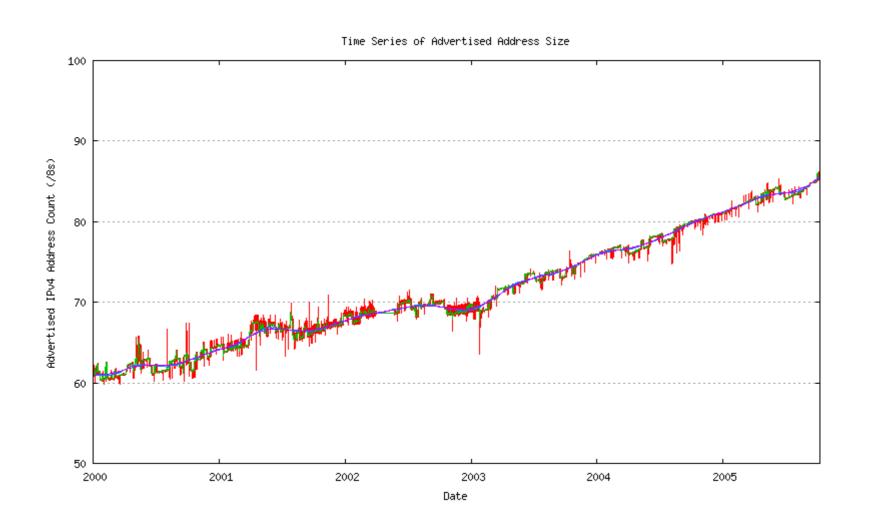

The approach used here

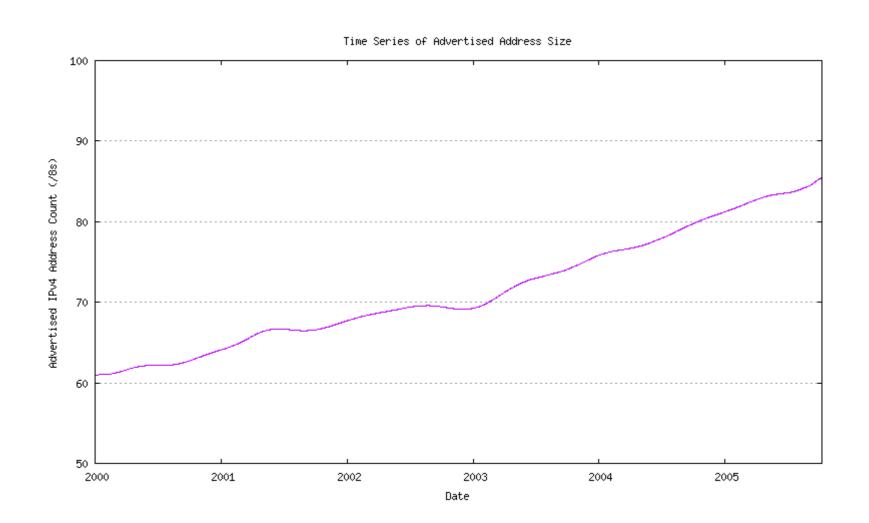

- The post-1999 data indicates that more than 95% of all allocated address space is advertised in BGP on the public IPv4 Internet
- This implies that the drivers for address consumption can be found in the advertised address pool behaviour
- From the advertised data time series remove the high frequency noise components, generate a best fit trend, then model interactions with unadvertised and RIR address pools
- Perform forward extrapolation from this model

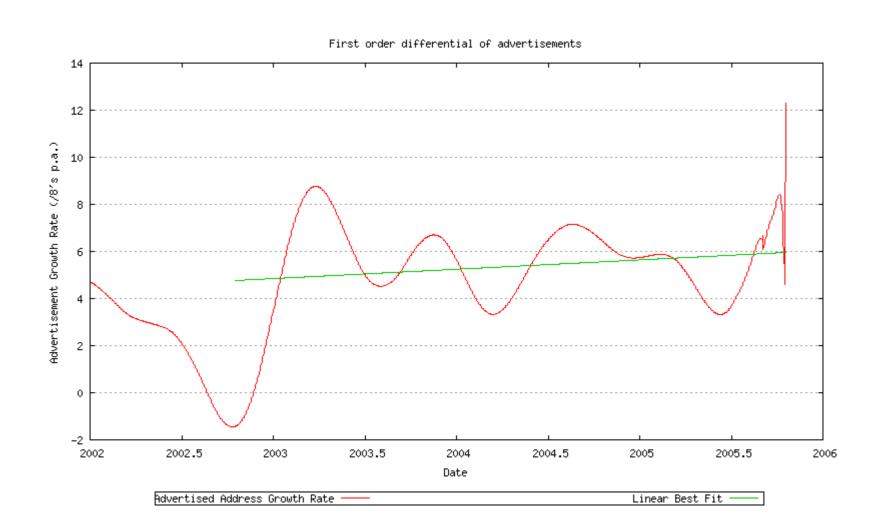

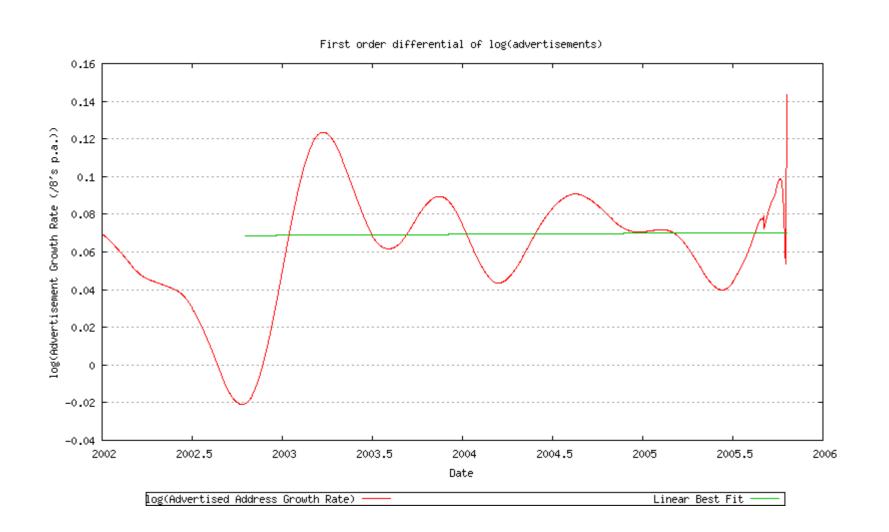

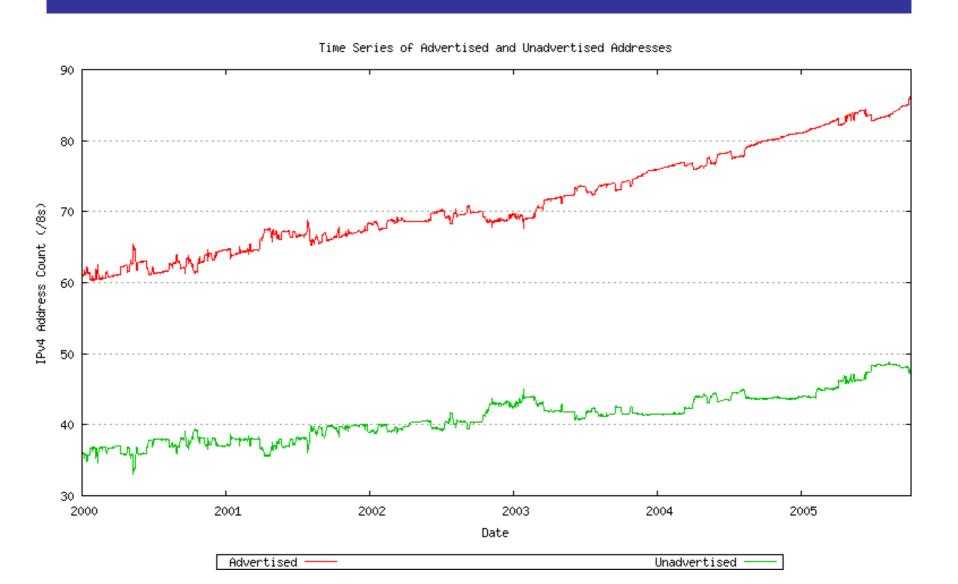

Advertised Address Growth

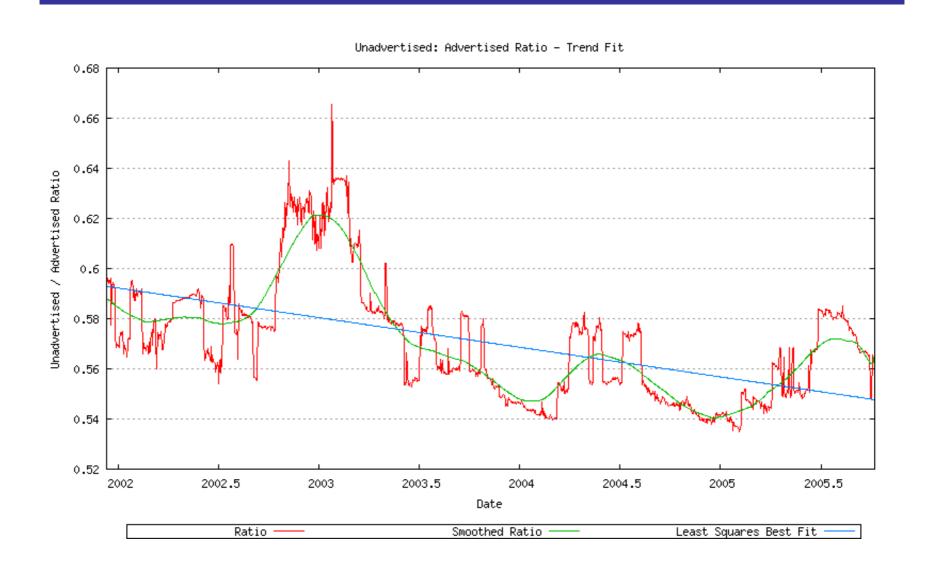

Advertised Address Growth

Unadvertised / Advertised Ratio

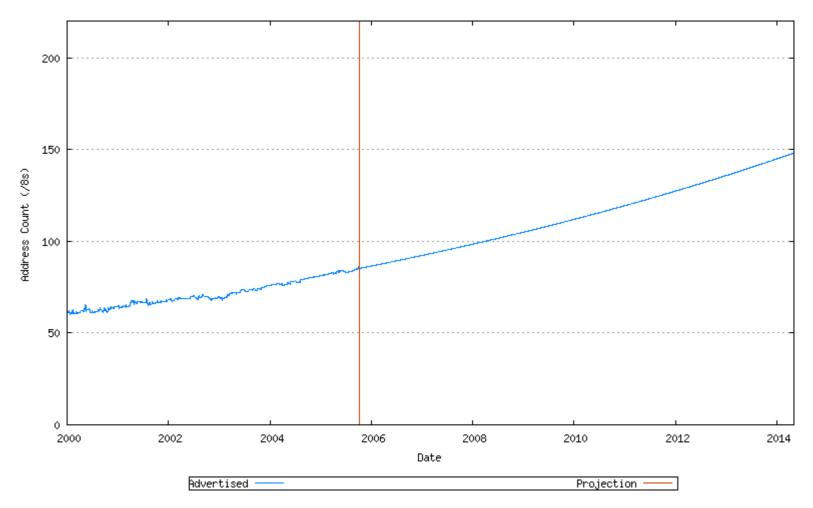

Modelling Advertised Growth

- Best fit to previous 3.5 years data appears to be a compound rather than constant growth rate
 - Use an exponential growth model ($adv = e^{a^*x + b}$)
- Average network growth of some 6 /8's per year rising
- To reach an 'exhaustion point' the model uses:
 - an exponential growth trend model based on previous 1,200 days (~ 3.5 years) advertised address data
 - a (decreasing) linear trend growth model of the ratio of unadvertised to advertised addresses
 - An assumption that the pooled "various" blocks will be exhausted following IANA pool exhaustion

Advertised Addresses

Advertised addresses grow at an exponential rate

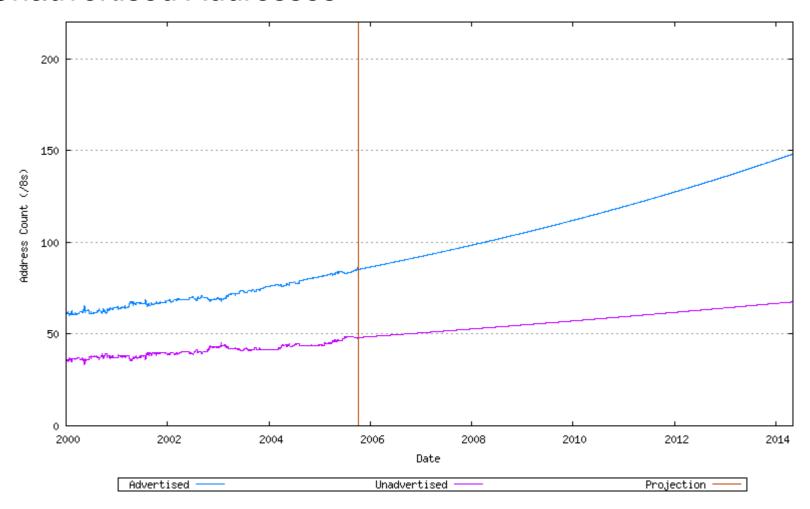

Advertised Addresses

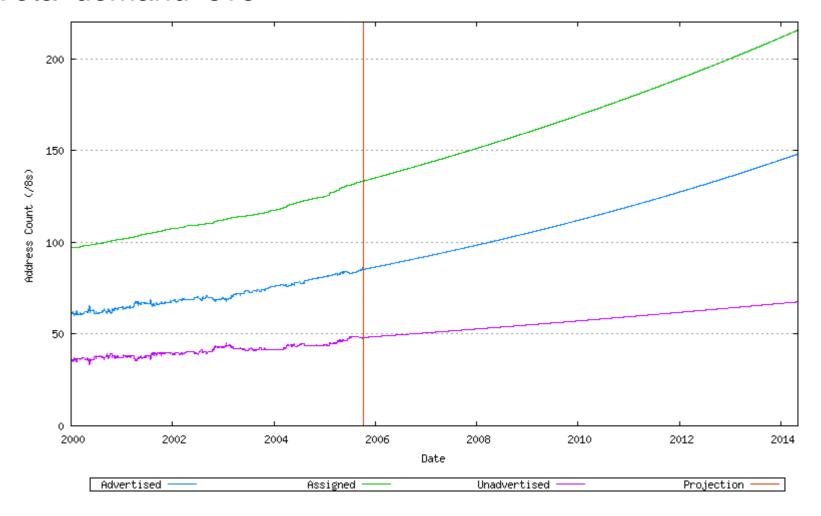

Unadvertised Addresses

- Unadvertised addresses grow at a slower exponential rate
- Reuse, reclamation and return rates for addresses drops to negligible levels

Unadvertised Addresses

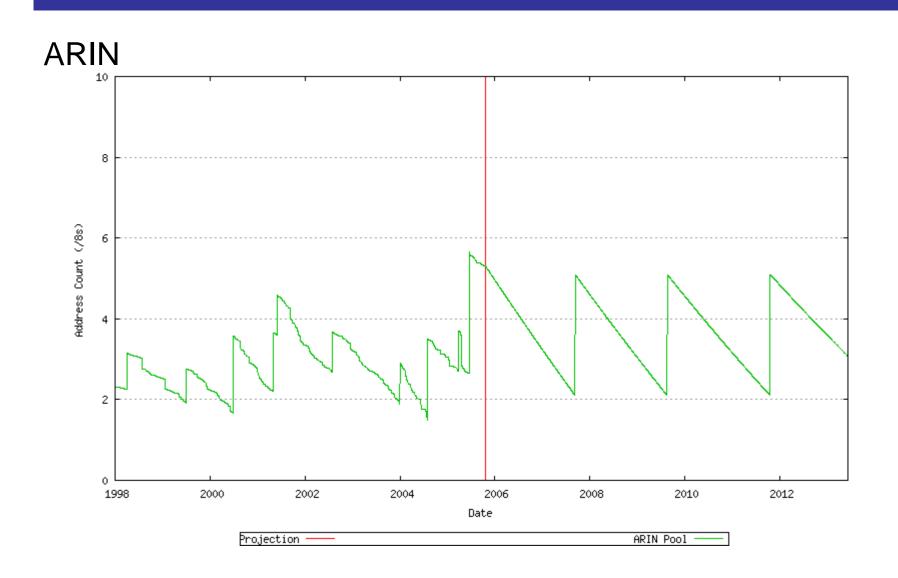

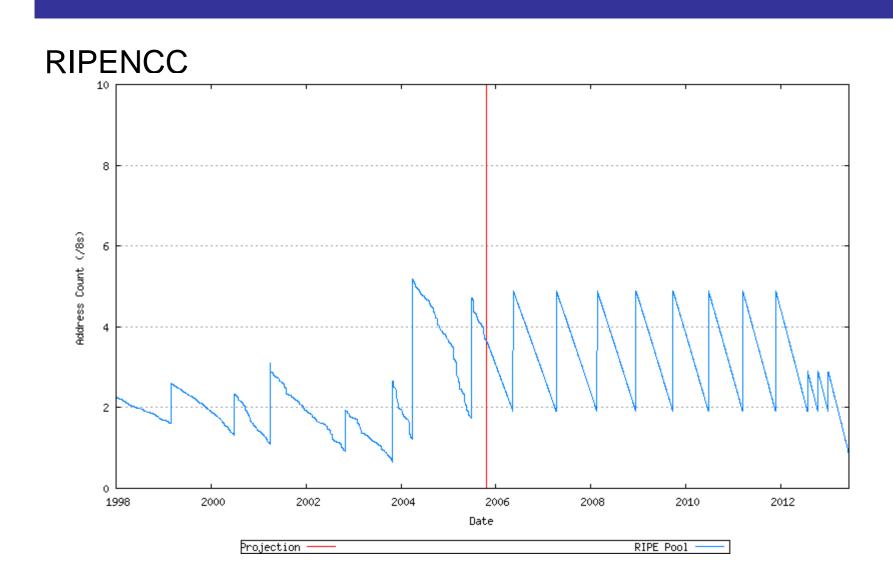

Total demand level

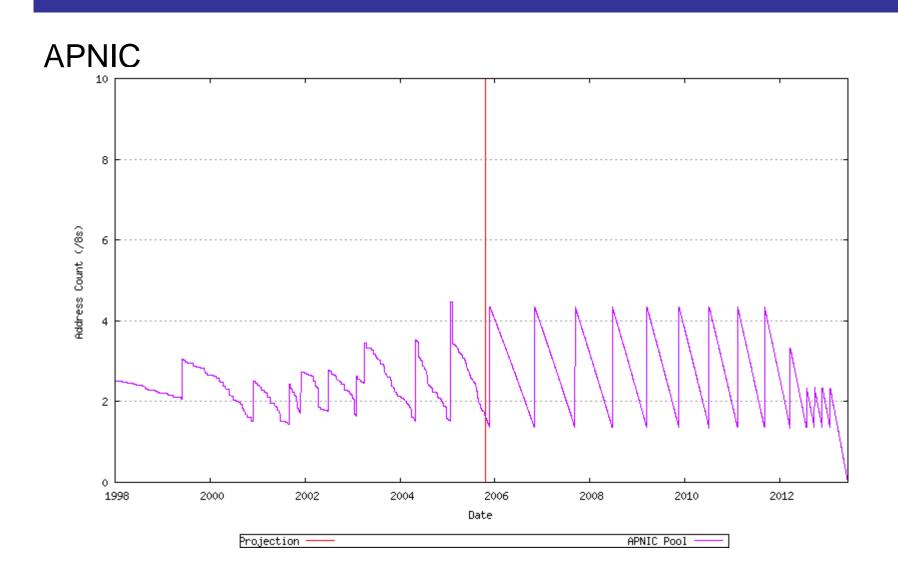

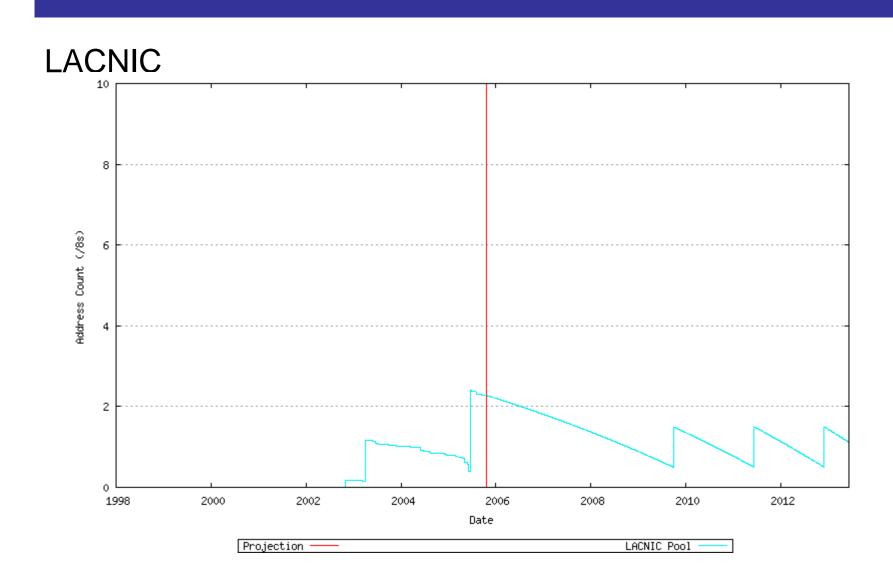

RIR Model

- Assumes that the relative rate of RIR allocation between the RIRs varies according to relative allocation trends in previous 3.5 years
- Absolute rate of total RIR allocations is driven by the total address consumption growth

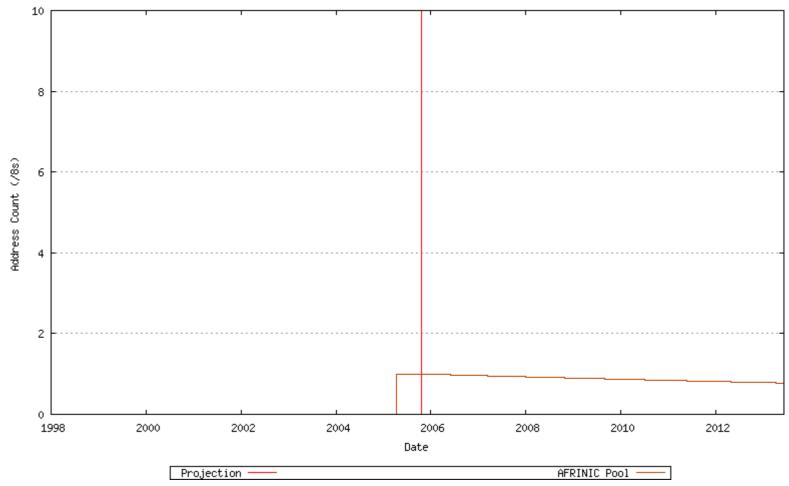

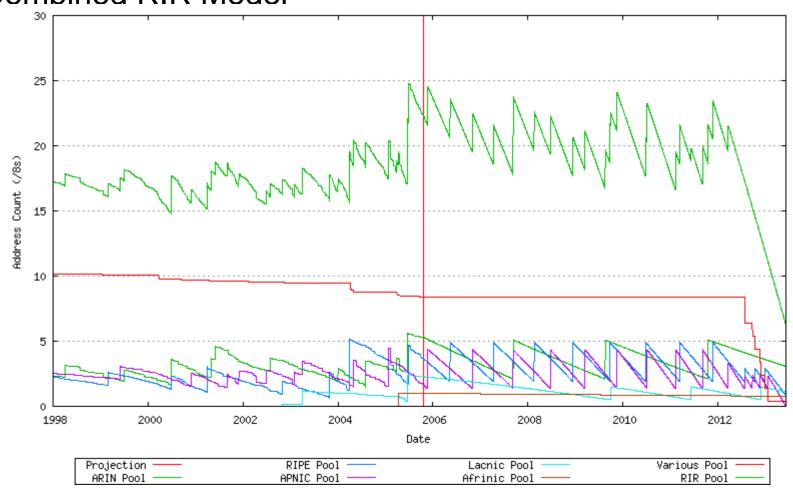

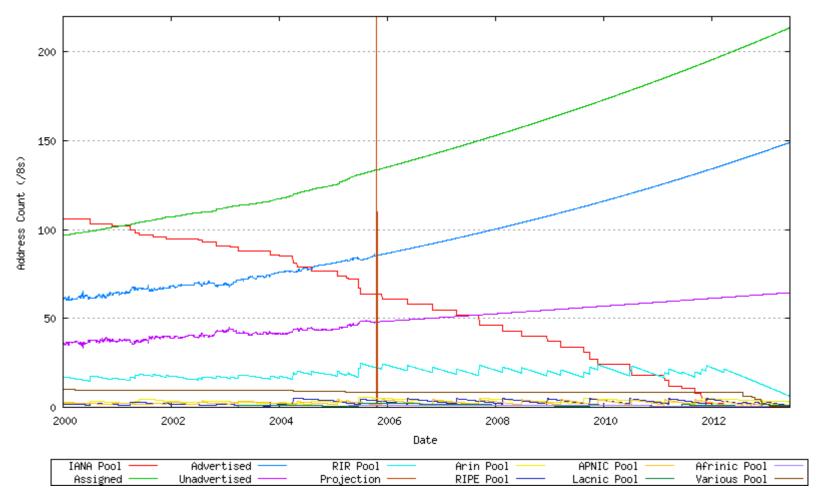

Combined RIR Model

Full Model

Some Projections from this Model

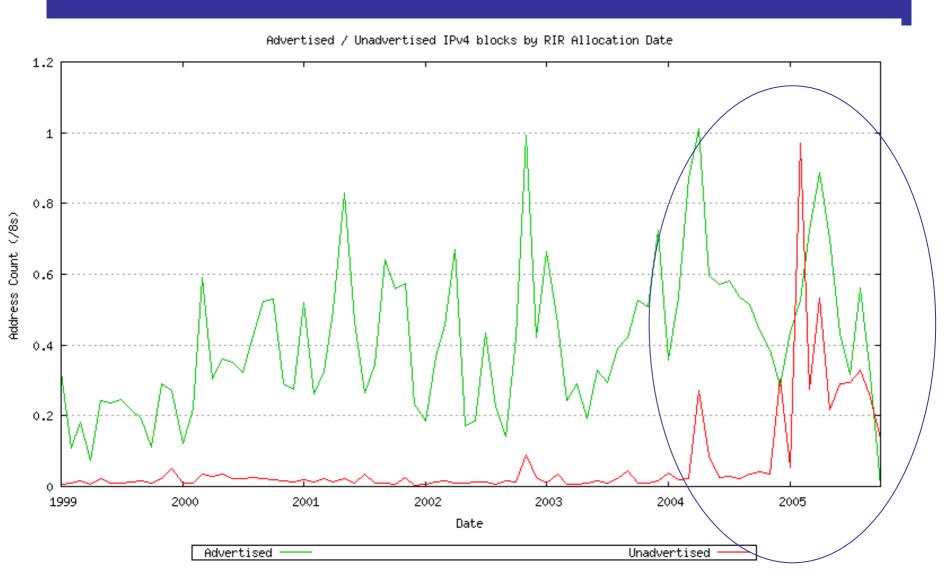

- IANA Pool exhaustion
 - 15 March 2012

- RIR Pool exhaustion
 - 4 June 2013

Comment

- This model assumes an orderly procession right up to the point of effective exhaustion of the unallocated address pool
 - This is <u>highly unlikely</u> to eventuate
 - Within the current policy framework a more likely industry response will be accelerating demands as imminent exhaustion becomes more 'visible'
 - It is not possible to model such 'last chance rush' behaviours based purely on the historical address allocation and BGP data
 - Some other form of modelling of social and market behaviour would be better positioned to make some guesstimates here

Early signs of a rush?

Commentary

- Exhaustion of the IPv4 unallocated address pool does not imply complete unavailability of IPv4 address resources to industry players
- The exhaustion of the unallocated IPv4 address pool does not appear to imply a forced IPv6 conversion onto the industry at that point in time
- There is strong reason to believe that the Internet industry will continue to use IPv4 as a base protocol long after this IPv4 unallocated address pool exhaustion date comes and goes

IPv4 Address Markets?

- In the absence of the imposition of specific external control functions, a conventional economic response would be the emergence of various forms of trading markets in address resources
- In conventional markets scarcity tends to operate as a pricing premium factor
- Market behaviours would then imply an entirely different behaviour in terms of IPv4 address distribution functions
- Unadvertised address pools, poorly utilized address pools and release of current address holdings based on conversion to address compression technologies would come into play within a market-based pricing dynamic
- What form of market regulation would be appropriate? How would it be applied? Who would apply it? Why would it be useful to have?
- How can we preserve address utility (the integrity of address uniqueness) in an environment of market-based trading?

Food for Thought

RIR Allocation Policies:

- What is the threshold point where the application of different IPv4 address allocation policies may be appropriate? Or is "no change" a wiser course of action?
- Should the RIRs establish "strategic reserve address pools? Why?

Emergence of IP Address Markets:

- Is the emergence of such markets Good or Bad? Avoidable or Inevitable?
 Appropriate or Inappropriate? Fair or Unfair?
- Are the any practical alternatives?
- How are trading markets best supported?
- Would such markets be regulated? How?
- What is the RIR role in such an environment?

Global Implications:

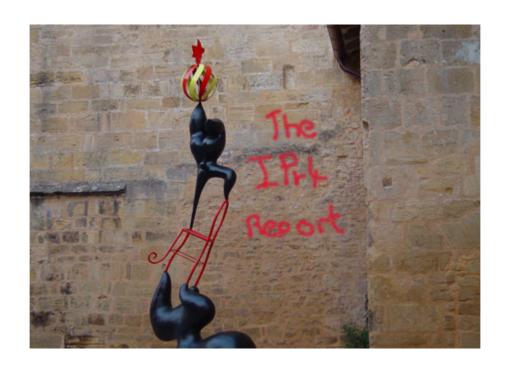

- What about "Equity", "Affordability", "Fairness" of access to address resources at a global level?
- And in what venue are such concerns best expressed?

Address Policy Questions

 What are most appropriate address management policy measures that will support the continued well-being of the global Internet and its users?

And when will they be needed?
