

The Resolvers We Use

Geoff Huston
APNIC

One of those wtf moments...

Like-vs-like: unsigned vs signed

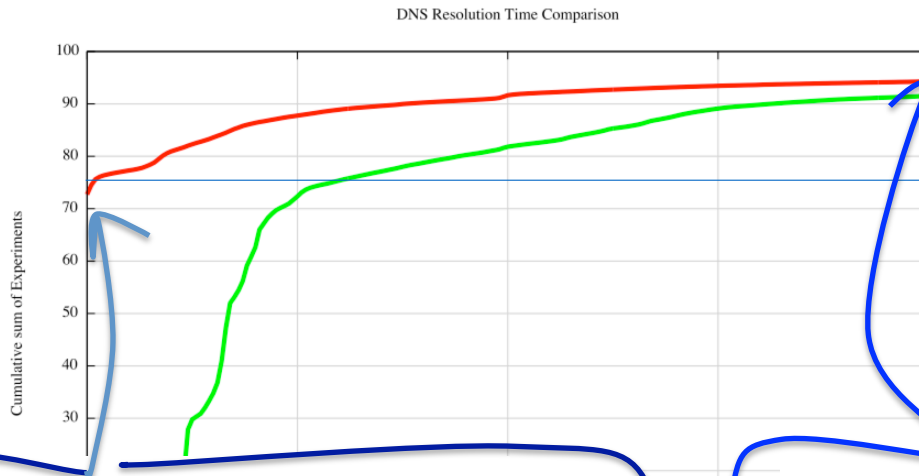

This figure was produced as part of some related work that was measuring the additional time penalty that would apply when the name being resolved was signed using DNSSEC.

One of those wtf moments...

Like-vs-like: unsigned vs signed

This figure was produced as part of some related work that was measuring the additional time penalty that would apply when the name being resolved was signed using DNSSEC.

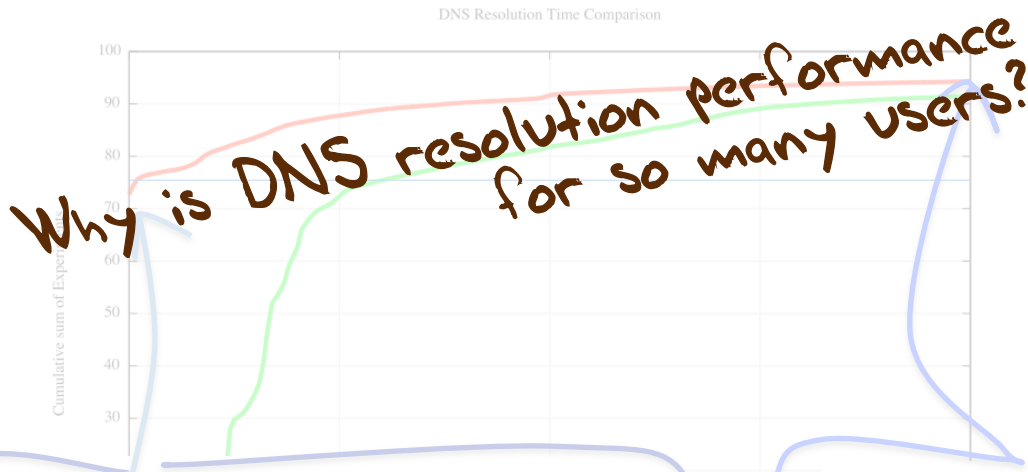

One surprising observation here is that for 25% of the world's users a simple uncached DNS name is not resolved in a single query

Some 6% of internet users use resolvers that take more than 2 seconds to complete the resolution function

One of those wtf moments...

Like-vs-like: unsigned vs signed

This figure was produced as part of some related work that was measuring the additional time penalty that would apply when the name being resolved was signed using DNSSEC.

One surprising observation here is that for 25% of the world's users a simple uncached DNS name is not resolved in a single query

Some 6% of internet users use resolvers that take more than 2 seconds to complete the resolution function

And that leads to...

- It appears that what we think about how the DNS works and how folk actually are using the DNS is not well aligned
- We all think we understand how DNS resolution works in terms of the interchange of DNS protocol elements
 - But the performance of DNS name resolution depends on a number of additional factors, both in terms of the users' choice of resolvers and the name admin's choice of authoritative servers

But...

The issue is more than just a question of unexpected poor performance of name resolution.

There's more to this...

Why is DNS resolution data valuable?

- Almost everything we do on the Internet starts with a DNS name resolution operation
- DNS resolver query logs contain a rich vein of real time information about what users do
 - query logs and can be analyzed to infer information about the users themselves through the names that their applications resolve
 - query logs contains indirect pointers that can be used to derive aggregate aspects of users' demographics, preferences, purchases, etc

Information Leaks

The question of where your DNS query traffic is being sent is also a question of whether you are leaking a real time trail of your online activities

Which leads to an interesting question about today's Internet:

- To what extent is this DNS resolution data stream “leaked” outward?
 - Across network boundaries?
 - Across national boundaries?

- This second form of information leakage is “interesting”

While many national regimes include regulations concerning personally identifying data, its not clear if these regulations extend these same protections to aliens who are not citizens of the country where the information is held

Measuring the Internet via its Users

At APNIC we've been using online ads to measure the user's view of the Internet for some years

- We ask users to fetch a unique URL
- This involves a DNS resolution and a HTTP GET to our servers
- So we collect sets of DNS queries and WEB queries
- To see
 - how we are doing with the IPv6 transition
 - where DNSSEC validation is being used
 - And similar

Users and Resolvers

These data sets also allow us to match

- the IP address of the resolver that queries the authoritative name server (the “visible resolver”)

to

- the IP address of the client agent that retrieves the URL

Some Numbers

Using data collected across 2014 (Jan-Dec):

104,986,719 individual sample points

404,705 unique resolver IP addresses

This “raw” data is skewed to the ad placement algorithms we used, so we then re-weighted the raw numbers in each country to align to the relativities of the Internet user population in each country. This provides us with a view that does not over-represent certain countries in the data

When we add origin AS it gets a little clearer

These resolvers are part of Google's Public DNS resolver farms that support 8.8.8.8 and 8.8.4.4 - they are the fetch slaves

So we need a different counting approach -- what if we group all resolvers by their AS?

Top Resolvers by Origin AS

25	8708	1,272,774	0.56%	64.98%	RCS-RDS RCS & RDS SA,RO

This list still looks pretty strange!

The problem is that resolver farms amplify their presence in this list because they splay multiple instances of the same query across slave resolvers

Can we compensate for this?

Google's

no direct queries to Google

Why is this happening?

- ❑ A lot of this story is Google's Public DNS, which now has a "market share" of more than 10 % of the Internet's user population
- ❑ User's efforts to circumvent content control via national DNS filtering measures
- ❑ Also there is users' efforts to circumvent DNS-based geo-loc content access controls (think Netflix)
- ❑ 3rd party DNS query monitoring/stalking (yes, there is some of this going on, but that's a lightning talk for another time!)
- ❑ Virus contamination of the host (yes, captured systems often show a redirected DNS config)
- ❑ <insert your favourite theory here>

Where is the DNS heading?

- Is the DNS under pressure to aggregate to ever larger resolvers and server farms?
- What is the economic model of name resolution in a highly aggregated environment? Will resolver operators turn to data mining of queries to generate revenue streams?
- Is it possible to reduce the information exposure while still using common resolver caches?
- What is the nature of the trade-off between resolution performance and information leakage in DNS resolution?

Thanks!
